ABSTRACT

Lions, Tigers, and Bears, Sky High!

by

Andrea Manning

The vertical zoo is a new zoo typology that rethinks both the organizational strategy of the traditional urban zoo and the tower building typology. By stacking the exhibits vertically the zoo program pushes exhibit organization in a new direction, providing opportunities for experiences not possible in traditional urban zoos. In addition, vertical stacking of the program is more efficient, taking advantage of the characteristic behaviors of heat, water and light to guide exhibit group organization. Furthermore, the verticality of the zoo program enables the zoo to become a more visual presence in an already dense urban environment. The new spatial organization of the zoo is accomplished through a reconfiguration of the systems integral to a traditional tower: the centralized core, the repetitive floor plate, and the nonspecific skin system.

ACKNOWLEDGEMENTS

To Greg, without whom this would have been impossible.

To my director, Clover Lee, who's support and dedication and patience meant everything to the development of this project.

To my dad, Jim, who refused to come down here and get the degree for me.

To my mom, Marlynn, who got me where I am today.

To Nick, who always believed in the project.

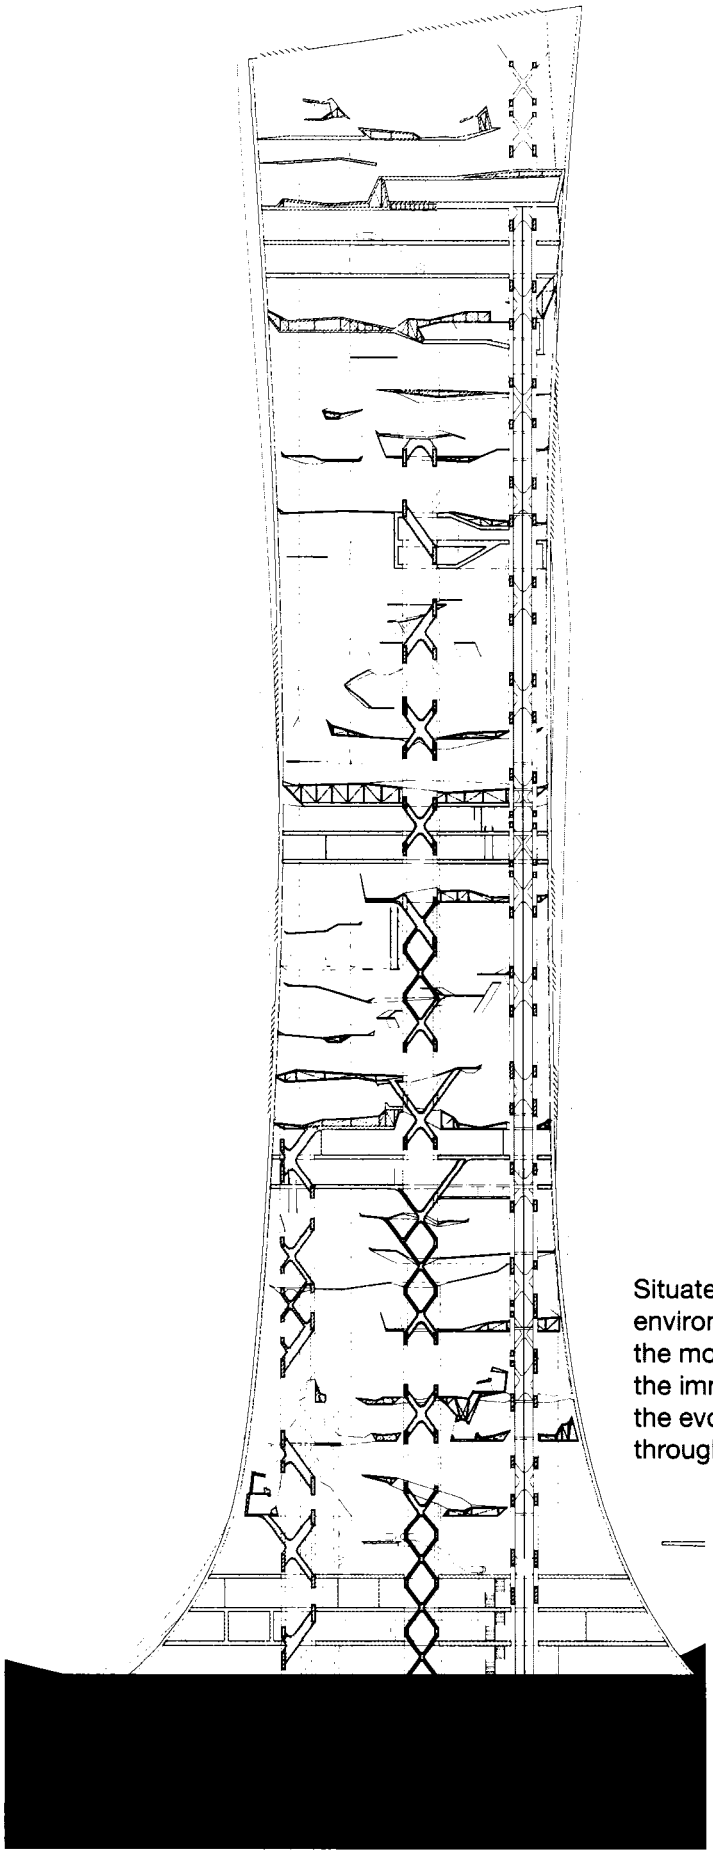
To Albert, who always gave the best advice at just the right time.

TABLE OF CONTENTS

Modern society lives on top of nature.
Charlene Spretnak

Zoos are urban institutions. Originally parks on the city edge urban dwellers could visit when city life became overwhelming, it was a but a short time before zoos were enveloped in rapidly sprawling urban development.

For centuries zoos have provided unique opportunities for education, entertainment and research not found elsewhere in urban centers. In the last century, as knowledge of the natural kingdom changed and grew, zoos responded. Owned and operated by municipal governments, the initial responses of zoos to change were conservative. Today zoos are operated by private and not-for-profit companies and must compete for money and attention within urban and suburban settings. To woo visitors, zoos are changing in ways more radical than ever, creating and simulating entire environments into which the zoo visitor is immersed.



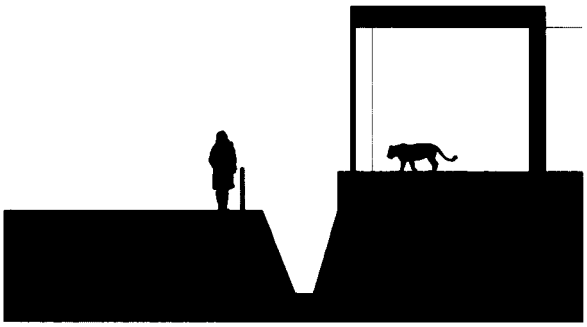
Situated in an extremely dense urban environment, the vertical zoo examines how the most successful exhibit type to date, the immersion exhibit, can continue to push the evolution of the zoological institution through stacking.

The history of the zoo: 3 exhibit types

How zoos have changed in time is reflected through the evolution of the exhibit typology. Exhibit evolutions are systemic and alter the zoo at three scales:

1. the specific exhibit
2. the grouping or organization of multiple related exhibits
3. the organization of exhibit groups on the scale of the zoo itself.

In the thousands of years that zoos have been urban institutions, there have been to this time only three polemical shifts in the evolution of the exhibit typology.

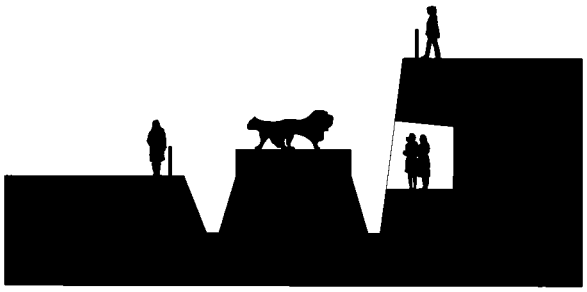


1 *Elevational exhibit*

The first milestone, the elevational exhibit, occurred in 1828 with the opening of the London Zoo. The elevational exhibit is defined by the perception of the exhibit through its frontal elevation. This scheme originally placed animals in a neutral environment, separated from the observer by an obvious barrier (i.e. iron bars or a visible moat). In the elevational exhibit scheme the animal and the observer have a one-to-one relationship. Elevational exhibits were often arranged linearly and according to taxonomy. These exhibit groups were further arranged according to animal family similarities.

1828

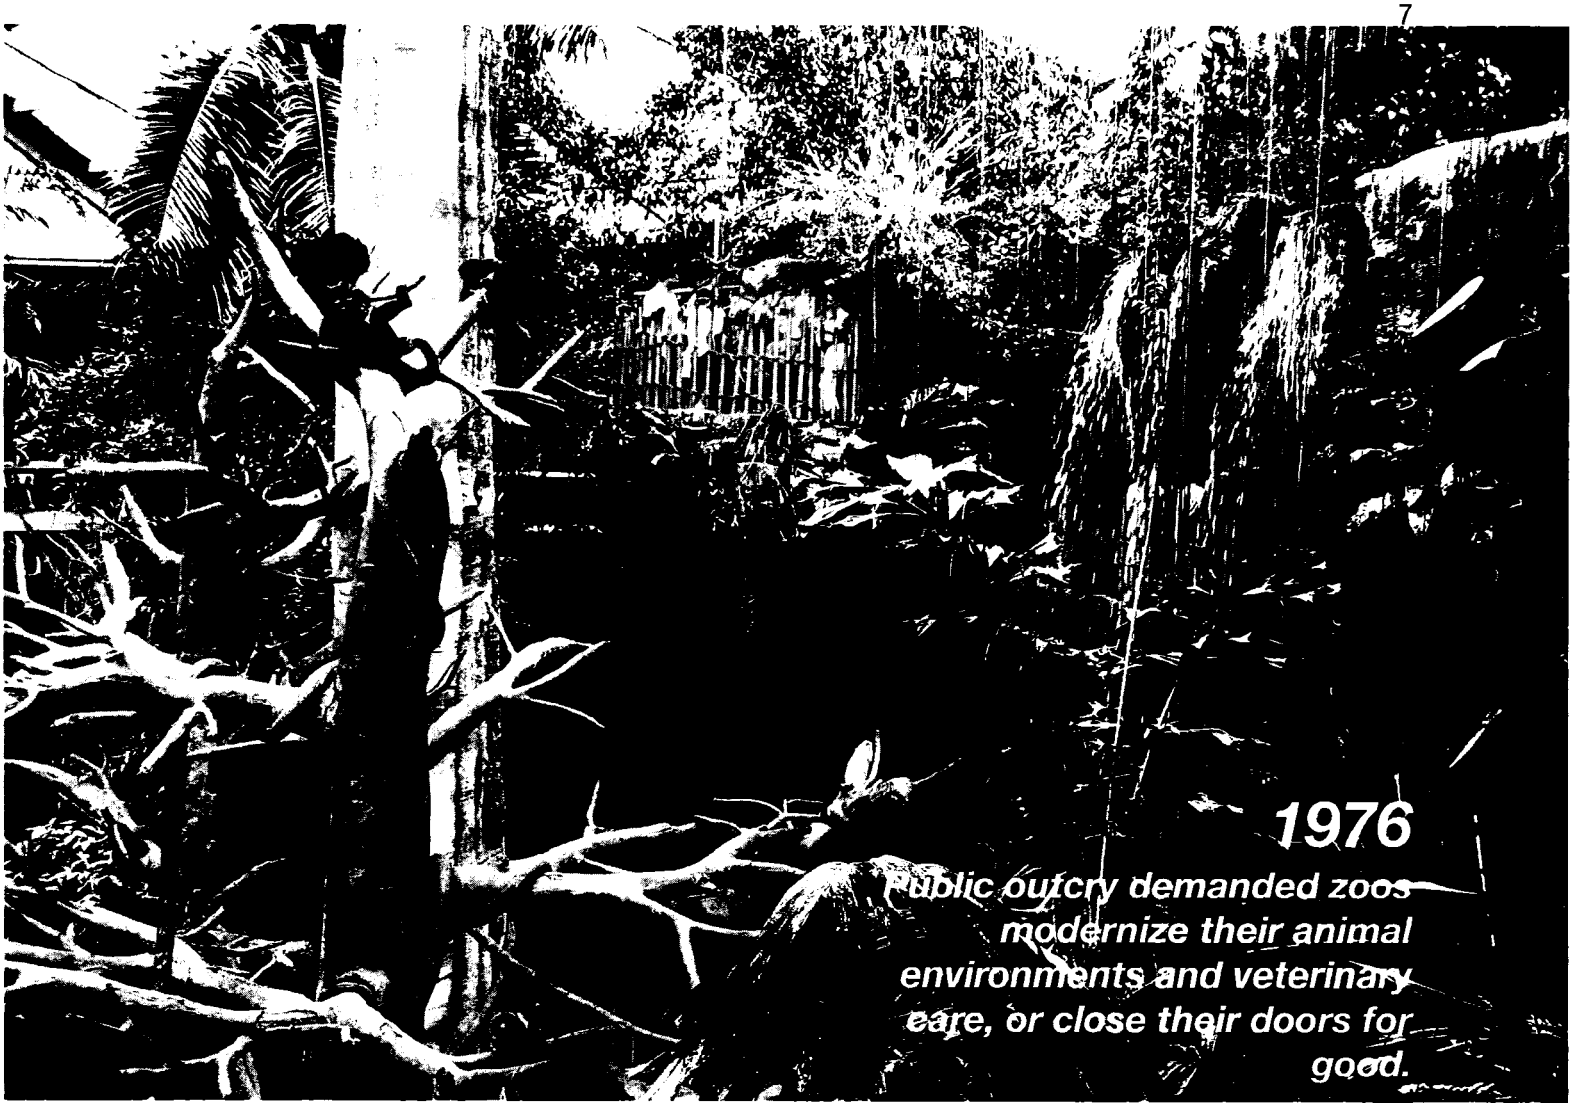
The London Zoo opens in Regent's Park. The world's first Zoological Gardens, the London Zoo was predicated on creating a scientific establishment for "teaching and elucidating zoology, and no public menageries..." (Hancocks)



② *Perimeter exhibit*

The second milestone, the perimeter exhibit, first opened in the late 1960's. This exhibit type did not replace the elevational exhibit but was added to the repertoire of zoo exhibit types. Like theater in the round, this type of exhibit enables observers to view animals from several different perspectives located around the exhibit enclosure, with views from above, below, over or under.

This scheme places pairs or small groups of animals in a naturalistic setting either indoors or out, separated from the observer by artifice and invisible barrier such as height or hidden electrical wire. In many cases perimeter exhibits were and are arranged according to country of origin. Groups of exhibits arranged by country of origin are often further organized with complimentary climatic zones adjacent to one another.

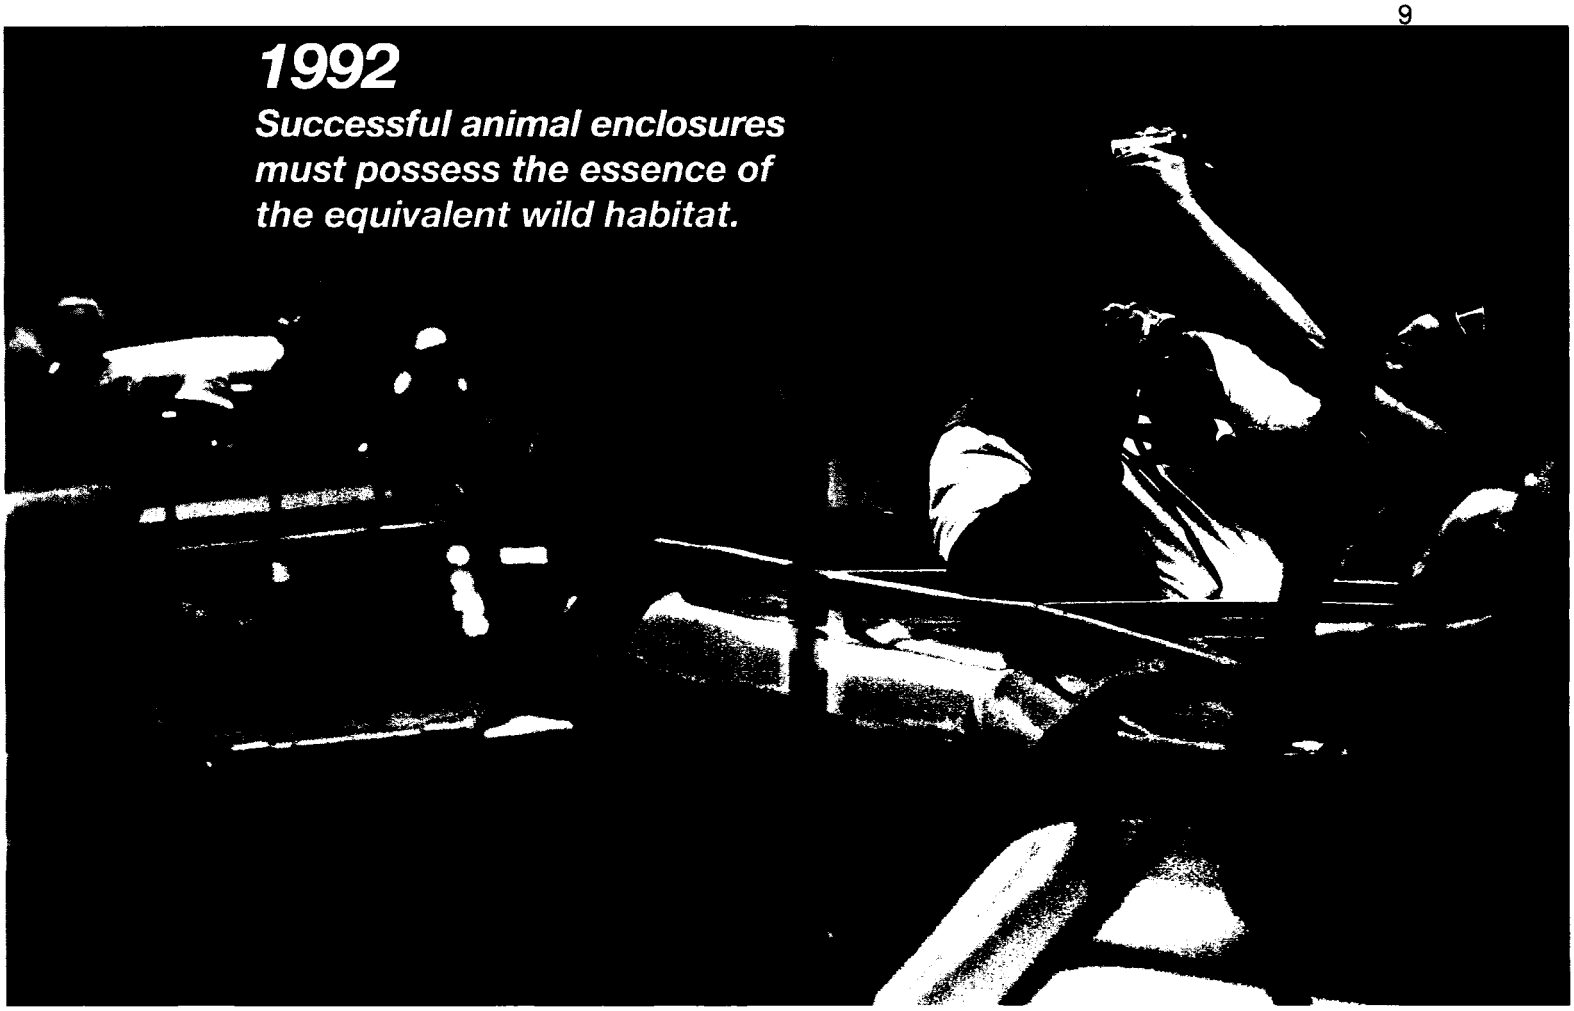


1976
Public outcry demanded zoos modernize their animal environments and veterinary care, or close their doors for good.

3 *Immersion exhibit*

In the early 1990's, the immersion exhibit scheme was added to the zoo exhibit catalog. The focus of the immersion exhibit is to recreate the natural setting and behavior of the animal inhabitants. Different from the previous two exhibit schemes, the immersion scheme locates the observer within the animal enclosure, looking outwards to the animal and exhibit borders beyond. The scheme places typical species groups in a setting reliant upon both natural and artificial ground condition and vegetation, again separated from the observer artifice and invisible barriers.

Similar to the perimeter scheme, immersion schemes are typically arranged according to country of origin, but require a larger area than the previous exhibit types. Space permitting the immersion scheme may occur in either an indoor or an outdoor setting.



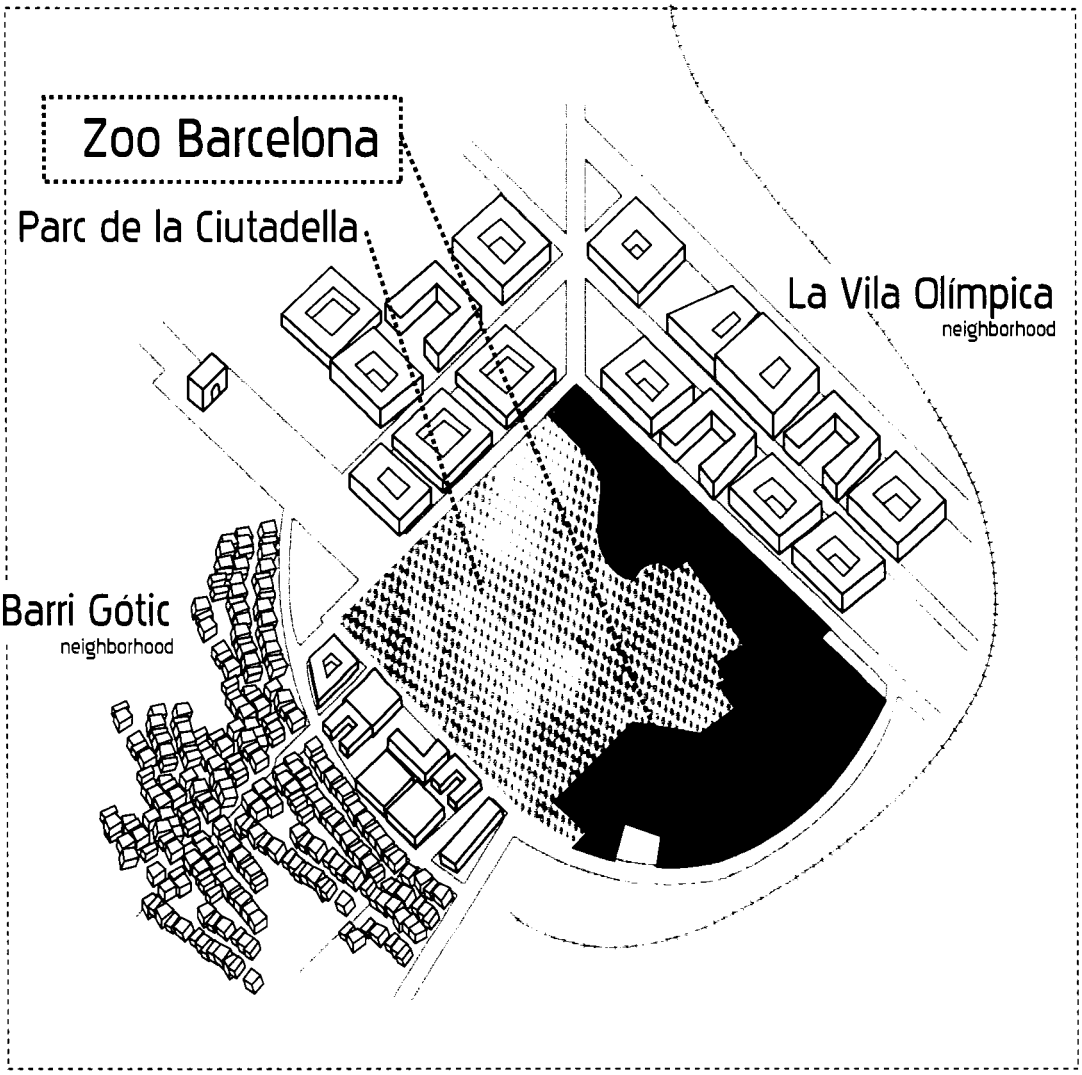
Of the exhibit types, the immersion exhibit scheme has been the most successful based on the following criteria:

1. animal health and welfare,
2. providing the zoo visitor with an experience that is entertaining and completely engaging,
3. and providing an educational experience, enabling the visitor to observe animals behaving in as natural a way as possible in an urban environment.

However, this model of immersion exhibit is difficult to implement in dense cities because of its large area requirement.

Zoo in the city

Most zoos rely on nothing but a very thin line of park space to both delineate and protect the zoo from its urban environment. This thin park line also means the zoo has little to no room to grow outwards and thus must seek other ways in which the immersion exhibit experience can be provided.



While the north and east edges of the zoo are buffered by the Parc de la Ciutadella, the south and west edges are bounded by the neighborhood, La Vila Olimpica. A 4m stone fence and zoo exhibit buildngs are the only barriers between the zoo and the adjacent urban environment. The audio and visual presence of the city is apparent continuously along the eastern edge of the zoo.

Zoological networks

Many zoos have specialized and institutionalized into zoological networks in order to find the space that enables the network now, instead of the independent zoo, to provide the full immersive experience. The network is composed of newer zoo typologies that function alongside the traditional urban zoo:

the wild animal park

the regional park

the endangered species park

and the aquarium.

These zoological institutions are then united to form zoological networks, examples include CRES (Conservation and Research of Endangered Species) that includes the San Diego Zoo and Wild Animal Park, and the WCS (Wildlife Conservation Society) network that includes the Bronx Zoo, three other New York City zoos and an aquarium.

One of such networks is Zoo Net, Tokyo's zoological network. The vertical zoo is situated in very dense and very active Shibuya Ward, in Tokyo. Zoo Net includes five other zoo institutions:

a traditional zoo

a regional zoo

an aquarium

and two endangered species zoos.

Zoo Net is active in preservation and conservation efforts with other zoos worldwide. The vertical zoo is the new urban component for Zoo Net, much like the Bronx, London, or San Diego Zoos.

The future of the network: the vertical zoo

The vertical zoo is a new zoo typology intended to function alongside other zoological institutions in a zoo network.

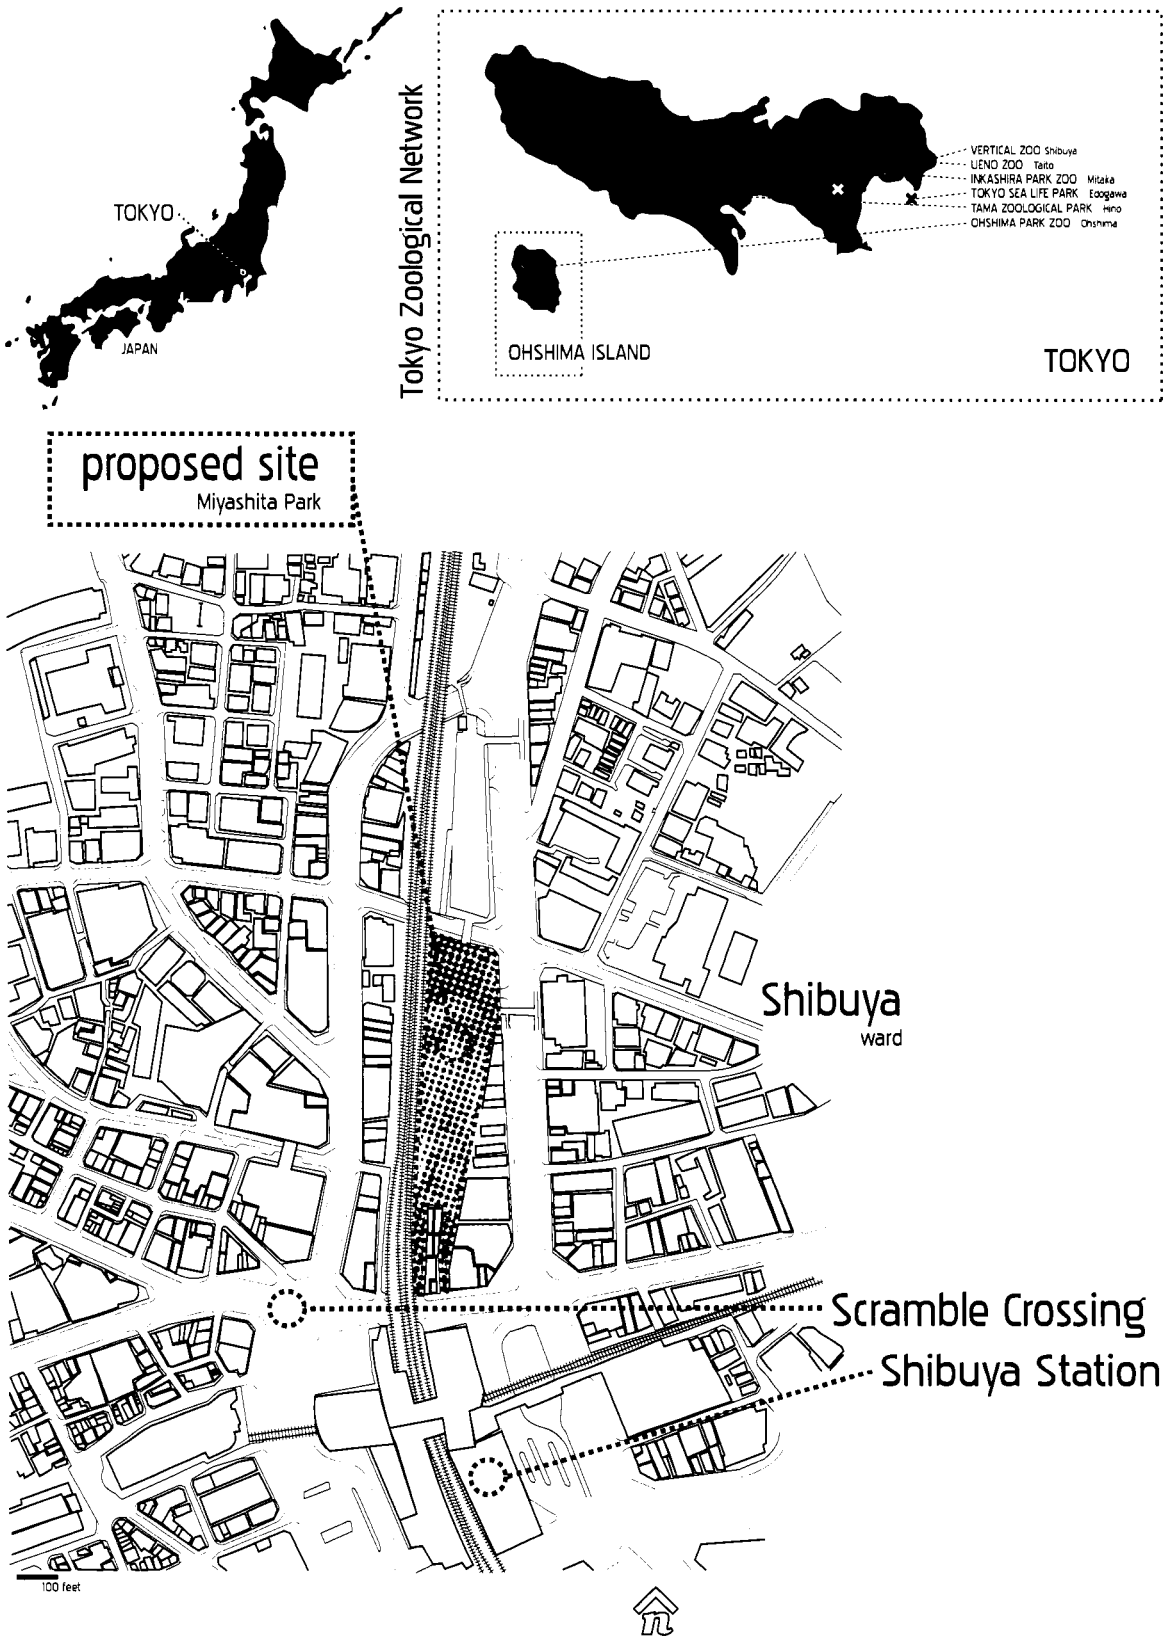
The vertical zoo rethinks the immersion exhibits spatial orientation and the relationships between various exhibits by stacking the exhibits and exhibit groups vertically.

Taking advantage of vertical space enables the zoo to maintain an urban site, which is important for visitor accessibility and crucial for a continued zoo presence in the city.

By enclosing immersion exhibits in an indoor setting, the zoo is able to recreate the many varied animal environments more accurately.

With the addition of the vertical zoo, a zoological network can redistribute its program more advantageously, improving exhibit space in all of the zoological institutions within the network.

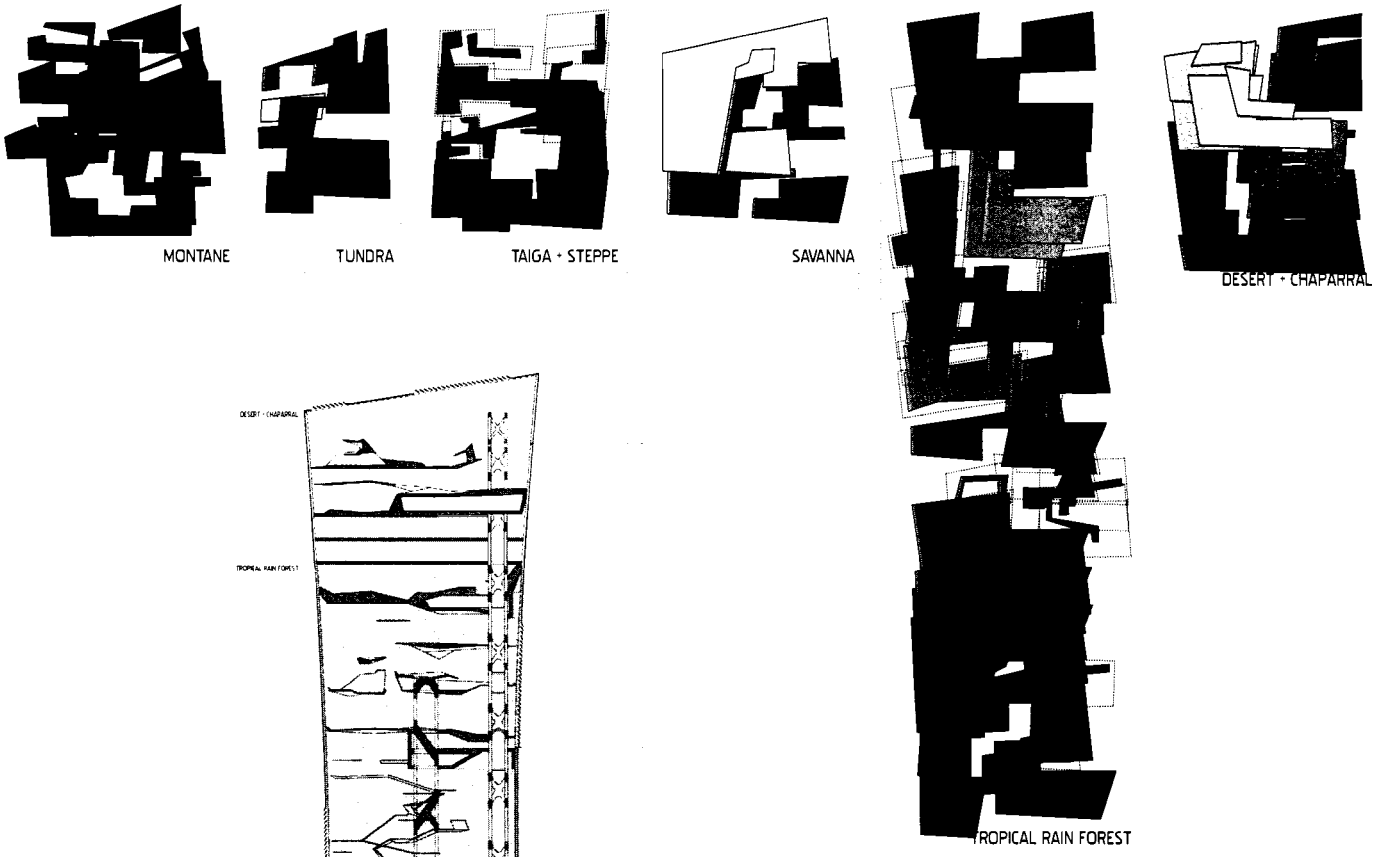
Vertical zoo site



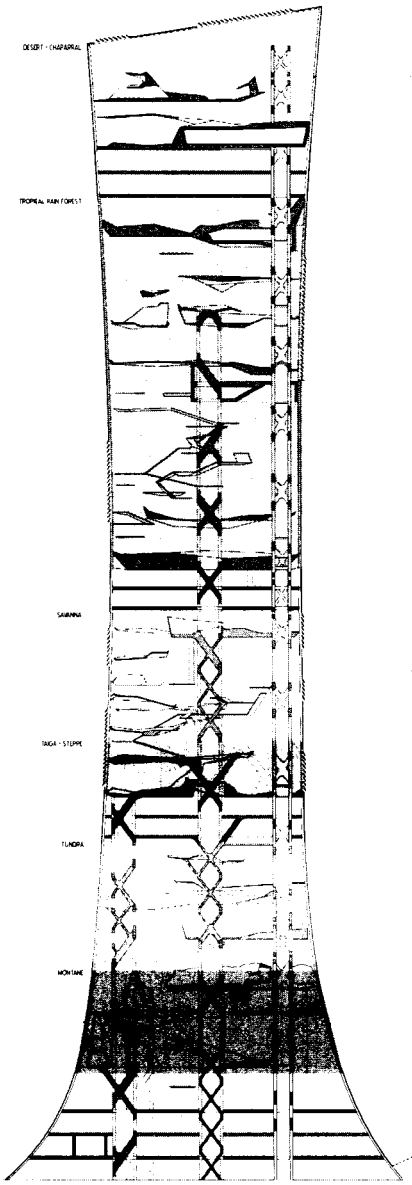
Programmatic organization

The vertical stacking of the immersion exhibits is a more efficient spatial model. Although the vertical zoo's site is only 2.4 acres, 80% of the vertical zoo's area is dedicated to exhibit space. This can be compared to traditional zoos where exhibit space is typically around 10% of the total site area.

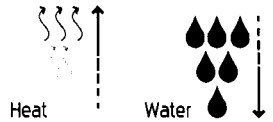
Vertical stacking of the immersion exhibits is also more energy efficient, taking advantage of heat rising and water falling. To this effect the exhibit program is organized according to bioclimatic zone. The immersion zones are then stacked in terms of the needs for more or less heat, more or less water, and more or less light. For example, in the vertical zoo, the Montane and Tundra bioclimatic zones that require cooler temperatures and less light are at the bottom of the tower, while the Desert Chaparral zone that requires significantly more light, much warmer ambient temperatures, and less water is at the top.



Program is arranged according to species
BIOCLIMATIC ZONE
of origin.

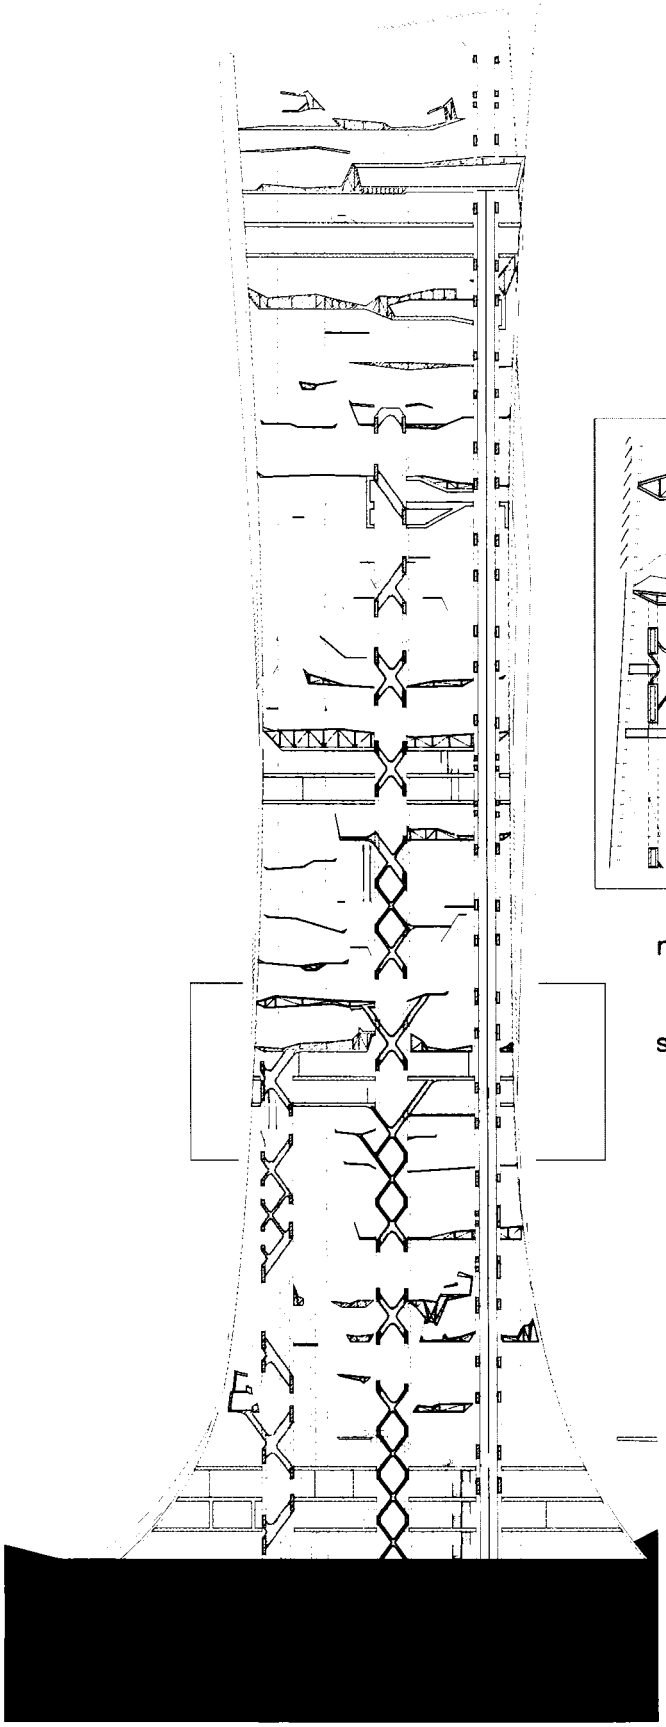


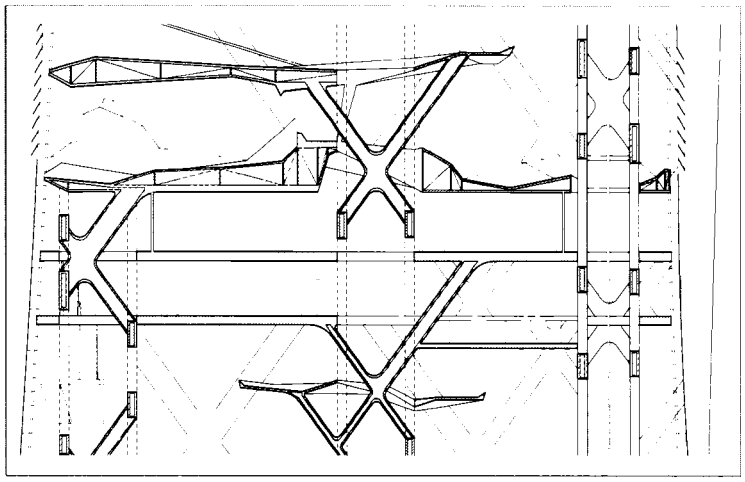
Bioclimatic zone stacking is more energy efficient, taking advantage of the properties of heat rising and gravity's pull downwards on water.



Structural organization

The bioclimatic zones are supported by a system of distributed structural cores that continue to different heights through the building and accommodate the different loading conditions and diverse spatial configurations of the various climatic zones. These cores utilize a dynagrid structure, a dynamic grid not uniform in aperture, to create super columns. These super columns require less structural steel, can more adequately support uneven loading conditions, and enable more light to move unimpeded into the building. Additionally, these cores enclose the intense mechanical support the zoo program requires. Further, the dynagrid of these cores branches out to help form the framework for the secondary structure that directly supports the exhibit armature and visitor circulation.





The cores utilize a dynagrid structure, a dynamic grid not uniform in aperture, to create super columns. These columns travel to different heights through the building and at moments, branch out to form the secondary structure that directly supports the exhibit platforms and the circulation.

Circulation

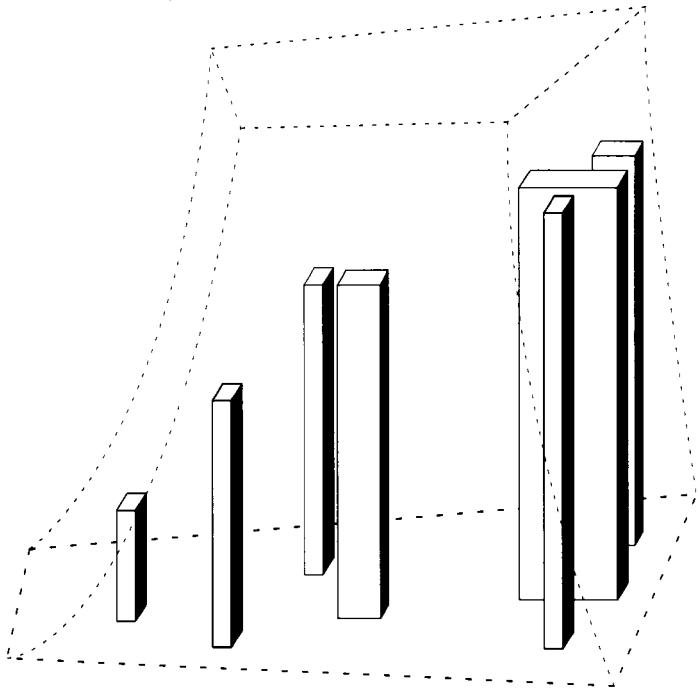
The zoo program requires multiple threads of circulation to occur and interact simultaneously. To accomplish this, the vertical zoo utilizes a circulation system consisting of a fast primary element and a slow secondary element. The primary circulation routes occur in tandem with the distributed structural cores. Each of these cores supports an elevator bank that ascends to different levels within the tower. These cores move people quickly to any of two types of destinations within the tower: transfer floors or intermediate floors.

Transfer floors are distinct from the bioclimatic zones and house the non-exhibit program of the zoo. These floors function as lobbies and support space. Here can be found cafés and retail boutiques, as well as staff administrative offices, education space and related facilities.

Intermediate floors are much smaller and are located within the bioclimatic immersion zones. These floors serve as launching platforms from which visitors move directly into a bioclimatic zone.

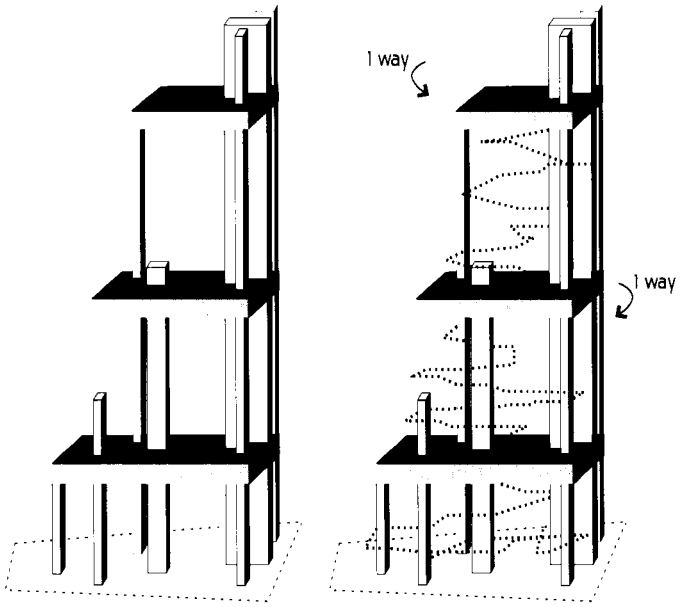
The secondary circulation route is accessible from both the transfer floors and the intermediate floors and consists of a series of catwalks, ramps, stairs, and escalators that move visitors among and through the immersion exhibits within the bioclimatic zones. Accessible from the secondary circulation are viewing platforms and short paths that take advantage of the vertical orientation of the space and enable visitors viewing vantage points that are typically not found in traditional zoos.

The structure and primary circulation are combined in 9 mega columns that ascend to different heights through the tower.

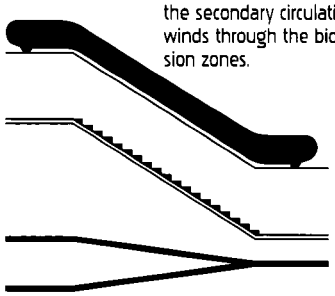


Relationship of mega column height to light penetration and filtration through the tower.

Within each dynagird mega column is an elevator bank that functions as part of the primary circulation core.



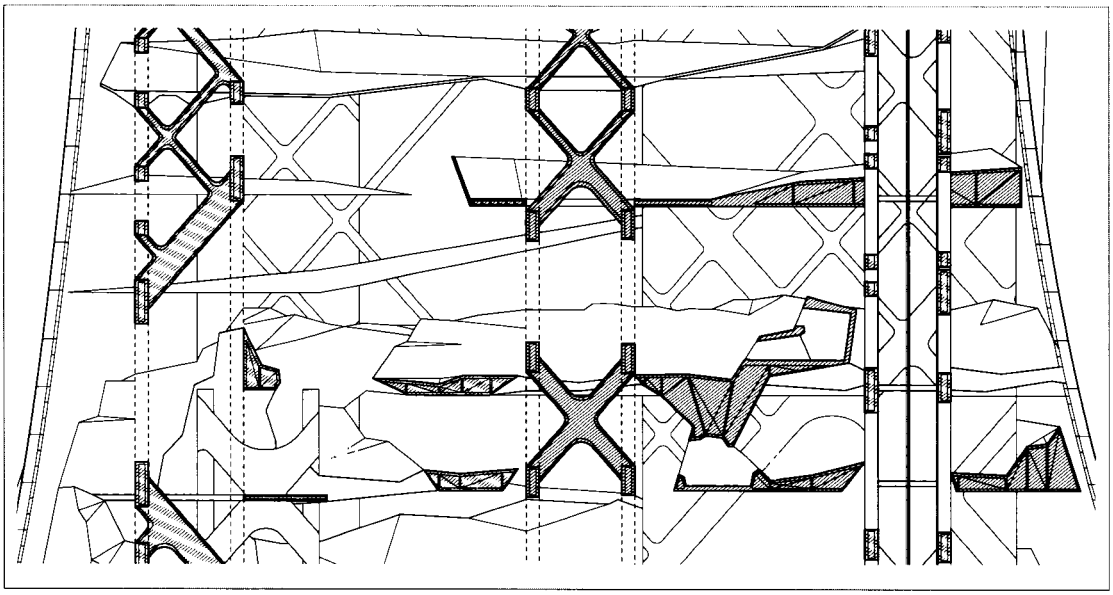
Escalators, stairs and ramps compose the secondary circulation system that winds through the biodimatic immersion zones.

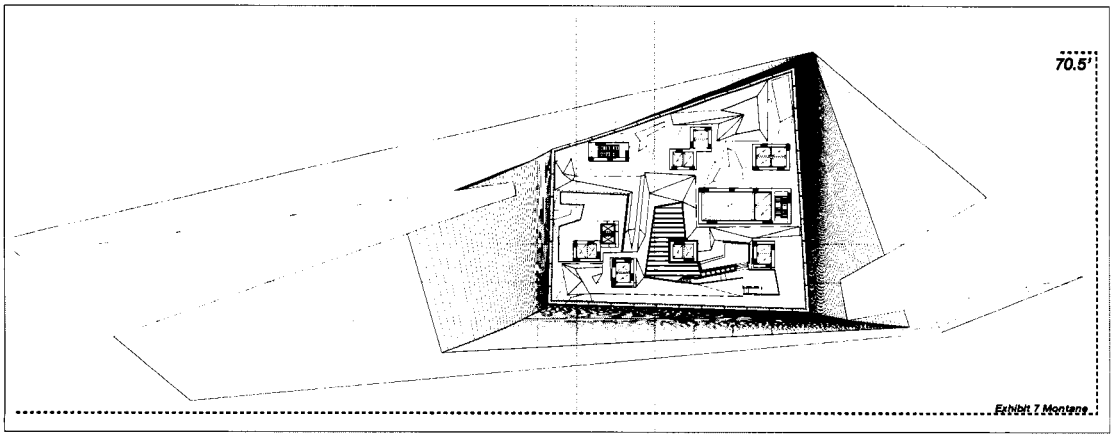


The secondary circulation is a one way path that winds downwards through each of the bioclimate zones, with entrance and exit points at each of the three transfer floors and the small intermediate platforms that occur at the upper termination point of each elevator.

Exhibit plates

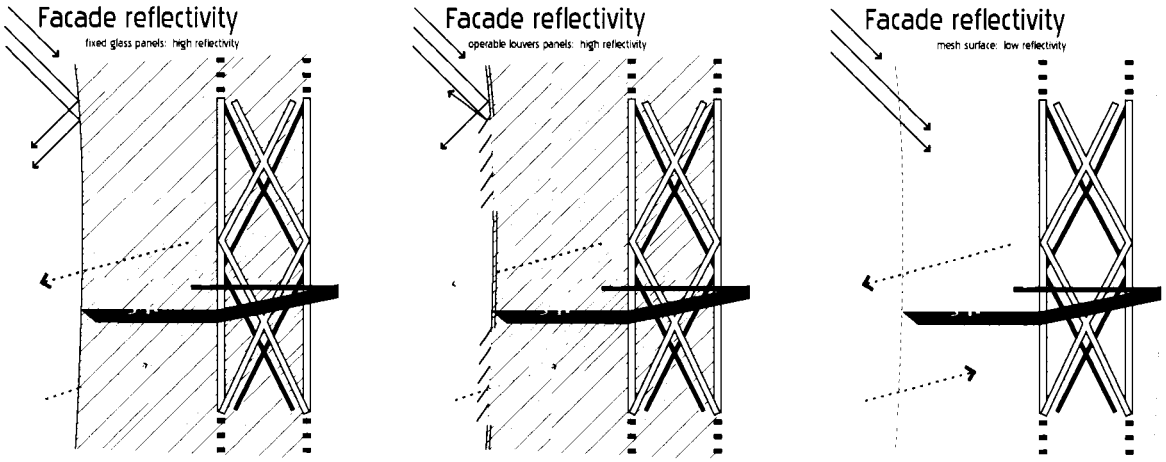
The exhibit platforms act as framework for the groundwork and vegetation that will later fill out the exhibit space. Conceived as plates that overlay a steel skeletal frame, exhibit platforms may become deep to create steep slopes for what will become mountainous terrain, as seen in the Montane bioclimate zone, or diversely may be thin with upturned edges acting as shallow trays to eventually hold soft ground matter like sand or mud. Exhibit platforms are not designed to be specific to an animal inhabitant, but rather to provide a substrate that can support the bioclimatic zone and the conditions typical to that zone in which it is located.





Skin

The exhibit platforms are contained by a double layer skin consisting of a glass exterior and wire mesh interior. This skin regulates the interior environment, as well as to determine what can be seen from within the exhibits looking out, and from outside looking into the tower. These conditions are achieved by alternating the arrangement of the glass and mesh components of the skin or by completely removing one of the components, such as the glass, leaving only a mesh exterior. Inoperable skin occurs in climatic zones that are incompatible with Tokyo's native environment, such as the Desert Chaparral zone. Operable skin occurs in climatic zones that are maintainable with exposure to Tokyo's climate. In the zones where the skin is operable, the exterior of the skin would require more technical support, and the skin's armature would appear heavier when viewed from within the inside. In certain zones the glazing of the skin will pull in entirely, leaving only the mesh along the surface of the tower.



Project boards

The vertical zoo is a new zoo typology that rethinks the spatial orientation of the immersion exhibit within the individual exhibit and between the groups of exhibits, the bioclimatic zones. By stacking the exhibits vertically, the zoo program is more efficient, taking advantage of the movement of heat, water, and light to guide bioclimatic zone organization - pushing exhibit organization in a new direction. The verticality of the vertical zoo tower enables the zoo program to become a more visual presence in an already dense urban environment.

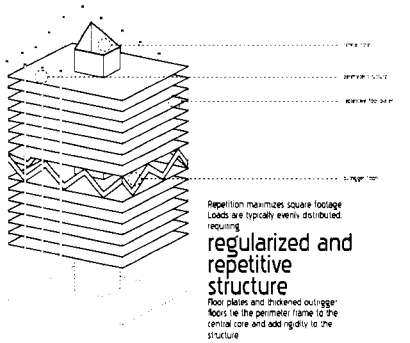
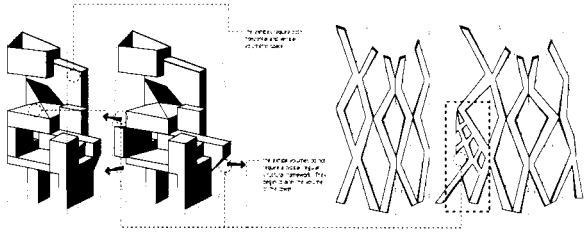
The tower + the zoo

EXHIBITS + ORGANIZATION in:



Repetition maximizes square footage
Loads are typically evenly distributed, requiring
regularized and repetitive structure
Floor plates and thickened outrigger floors tie the perimeter frame to the central core and add rigidity to the structure

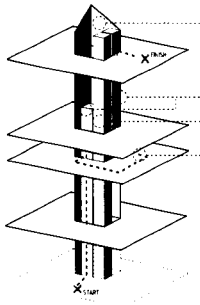


Unlike the typical tower structure, the vertical zoo utilizes horizontal and vertical planes for exhibit space. The zoo exhibits require
hyper specific volumes.

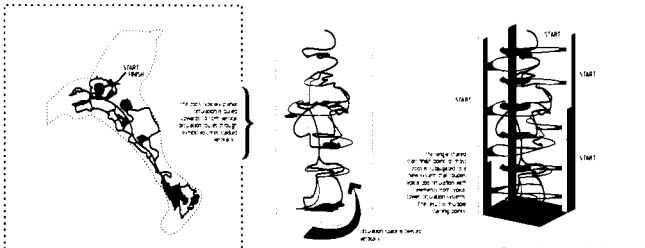
To meet the needs of the specific exhibits the structure of the tower can specialize, reflecting the uneven internal loading conditions of the program. The structural system employed does not have to follow the core-plate perimeter structure model; it can become deep providing structural support within

The structure of the vertical zoo is
specific and not regularized.

STRUCTURE



Tower circulation systems are designed to maximize the efficiency of
point to point travel
Tower circulations systems typically utilize both high speed and regular speed elevators for distance travel in conjunction with a series of transfer lobbies, or sky lobbies, as collection and redistribution zones, and a network of stairs or escalators for local travel.

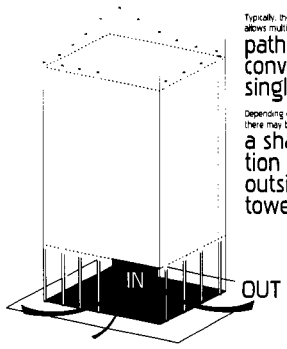


Unlike the tower, travel through the typical zoo has
no specific destination.
Additionally, travel through zoos typically takes place only horizontally

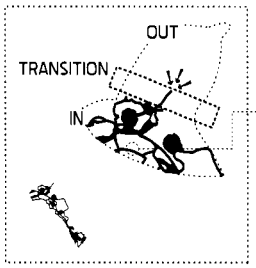
Circulation paths in zoos are typically circuitous and meandering, intentionally disorienting to the visitor. With many paths to chose from, visitors are less likely to be traveling one primary path increasing visitor distribution throughout the zoo, further enables the zoos to transport visitors to exotic locales

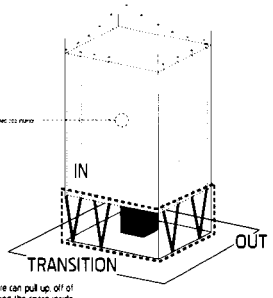
The vertical zoo can utilize elements of the typical tower circulation system to rapidly distribute visitors to "launching" destinations throughout the tower. From the launching floors, visitors can chose their own paths down, through the various exhibit spaces

CIRCULATION



Typically, the ground floor of the tower allows multiple
paths to converge at a single point.
Depending on the tower's program, there may be
a sharp transition between outside of the tower, and in.



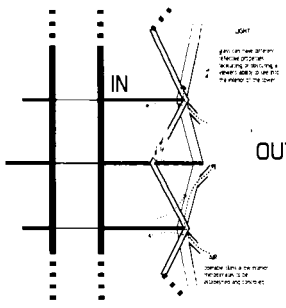


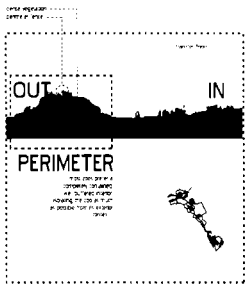
Unlike the tower, the entrance to the typical zoo is followed by passage through a
transition zone,
which moves the visitor from the outside world, into the contained world of the zoo.

Upon exiting the transition zone, visitors
convergent paths promptly diverge.

The tower structure can pull up, off of the ground, blurring the space inside the tower with the space outside of the tower. This will be the transition zone of the vertical zoo, and establish relationships between inside and out that are carried throughout the tower

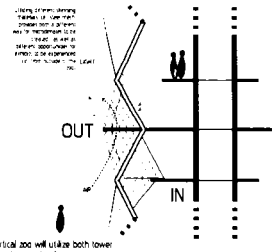
GROUND CONDITION





The skin of the typical tower functions as a system of
open containment,
regulating interior climate and providing and controlling views primarily outwards. Towers tend to focus visitor attention outwards, tying the tower into its urban context.

The perimeter of the typical zoo is the equivalent of the tower's skin. However the perimeter of the zoo institutes a system of
closed containment.
The perimeter of the typical zoo works as a buffer, isolating the zoo from its urban context, and focusing the attention of the visitor inwards.



The vertical zoo will utilize both tower and zoo technologies to create
alternating zones of open and closed containment.

Multiple levels of containment enable the vertical zoo to provide the essential animal environments, while simultaneously acknowledging its urban context.

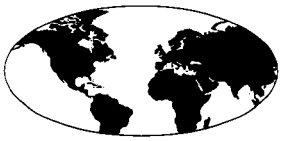
ENTERTAINMENT EDUCATION RESEARCH CONSERVATION



The Bronx Zoo is operated by the Wildlife Conservation Society. Since 1895 WCS has worked from the Bronx Zoo headquarters to save wildlife and wild lands throughout the world. They uniquely combine the resources of wildlife parks in New York with field projects around the globe to inspire care for nature, provide leadership in environmental education, and help sustain our planet's biological diversity. Today WCS is at work in 53 nations across Africa, Asia, Latin America and North America, protecting wild landscapes that are home to a vast variety of species from butterflies to tigers. Their pioneering environmental education programs reach millions locally, nationally and internationally. And the more than 4 million visitors who annually experience our Bronx Zoo, New York Aquarium and Central Park, Queens and Prospect Park Zoos are encouraged to learn about our natural world and inspired to care about its future.

London Zoo

founded in 1828

ENTERTAINMENT EDUCATION RESEARCH CONSERVATION

The London Zoo is operated by the Zoological Society of London, whose focus includes conservation, science, and learning. The ZSL is consists of five operating divisions that include the London Zoo, Whipsnade Wild Animal Park, Institute of Zoology, Conservation Programmes, and Fellowship Services.

The ZSL mission:

- To achieve and promote the worldwide conservation of animals and their habitats.
- Keeping and presenting animals at London Zoo and Whipsnade Wild Animal Park in accordance with best practice giving priority to species that are threatened in the wild.
- Increasing public understanding of animals and their welfare and of the issues involved in their conservation.
- Maintaining an outstanding education and information program, particularly for schoolchildren and families.
- Undertaking field conservation programs, both in Britain and abroad.
- Developing its role as a leading centre for research and conservation biology and animal welfare.
- Fulfilling its role as a learned society and 'force for zoology and animal conservation through publications, scientific meetings, lectures, the award of prizes for outstanding achievement and the promotion of conservation policy.

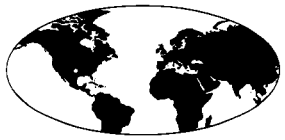
Fort Worth Zoo

founded in 1919

ENTERTAINMENT EDUCATION CONSERVATION



The Fort Worth Zoo seeks to strengthen the bond between humans and the environment by promoting responsible care of wildlife and ensuring diverse high quality education and experiences at and on behalf of the zoo. The three corner stone principles of the zoo are:
- CONSERVATION: through the facilitation of conservative and scientific study currently at work in 25 countries
- EDUCATION: providing factual information to nurture the appreciation of and respect for wildlife and the environment. The education department provides classes, camps, workshops, and out reach programs for people of all ages
- ENTERTAINMENT: through a commitment to excellence with the hope of always exceeding expectations

LOCATION: Fort Worth Zoo, Fort Worth, Texas
32° 43' N 97° 21' W
CLIMATE: Humid, subtropical

Zoo Barcelona

founded in 1892

ENTERTAINMENT EDUCATION RESEARCH

Zoo Barcelona adheres to the World Zoo Conservation Strategy for preservation, research and education. Zoo Barcelona collaborates on several international and European programs for breeding and preserving species, and contributes to many species reintroduction programs. The zoo is also involved in several diverse areas of research on many species of animals.

The Zoo Barcelona Education Department's primary focus is children, but the department offers programs for people of all ages. Promoting quality education experiences and opportunities is the zoo's primary social objective.

LOCATION Zoo Barcelona, Barcelona, Spain
41° 23' N 2° 11' E
CLIMATE Mediterranean, subtropical

CITY
AREA 24,809 acres
POPULATION 1.6 million

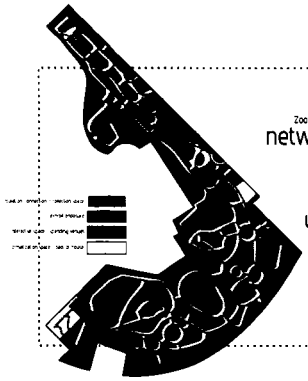
ZOO
AREA 35 acres
POPULATION 1.2 million visitors annually
7500* resident animals
400* species represented
* approximate

Zoo Barcelona's land area is
35 acres

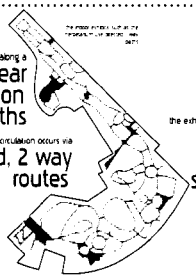
According to the population density of Barcelona, 7500 people equivalent number to animal residents at the zoo would require 117 acres
330% more area

* soccer field dimensioned at 120 feet x 360 feet = 86,400 sq ft or 1.987 acres

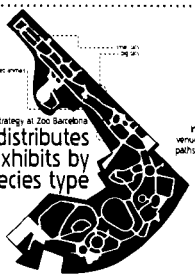
the equivalent area covers approximately
18 soccer fields



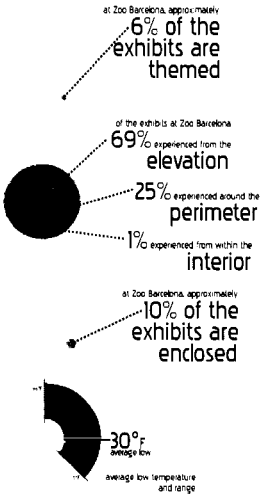
Zoo Barcelona is organized along a
network of linear circulation paths
almost all of the circulation occurs via
undirected, 2 way routes

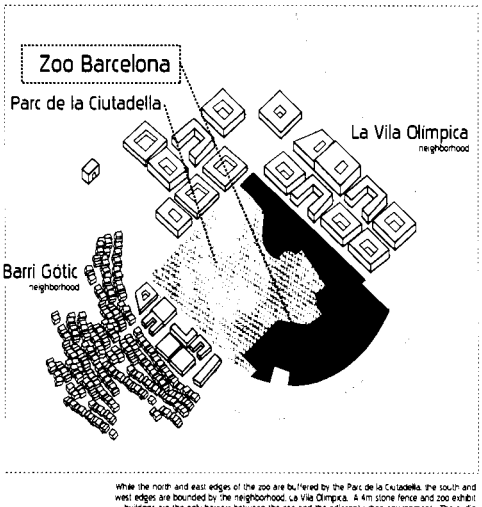


the exhibit strategy at Zoo Barcelona
distributes exhibits by species type



interactive space and spending venues occur along primary exhibit paths and are not themed into the exhibit environment





While the north and east edges of the zoo are buffered by the Parc de la Ciutadella, the south and west edges are bounded by the neighborhood, La Vila Olimpica. A 4m stone fence and zoo exhibit buildings are the only barriers between the zoo and the adjacent urban environment. The audio and visual presence of the city is apparent continuously along the eastern edge of the zoo.

Los Angeles Zoo

founded in 1964

ENTERTAINMENT EDUCATION CONSERVATION

The Los Angeles Zoo is committed to providing an interesting and educational experience for visitors and excellent living conditions for residents. The zoo participates in conservation programs with the aim of preserving native habitats. The Los Angeles Zoo also offers local educational outreach programs, camps, lectures, zoo shows and activities.

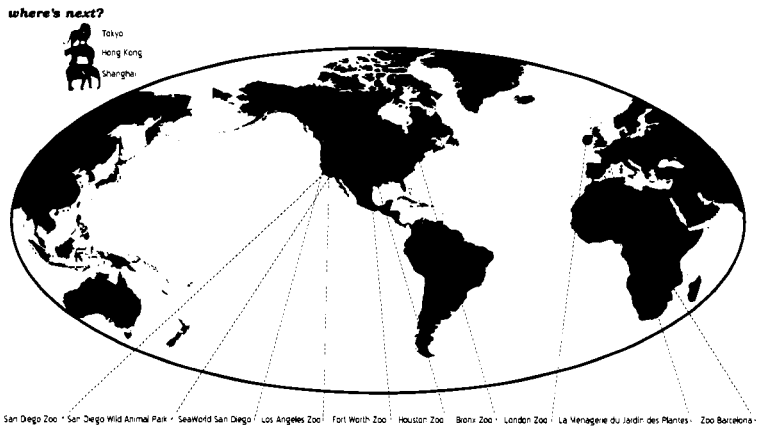
Case study analysis



Zoos are urban institutions. Originally intended to be parks on the city edge to which urban dwellers could visit when the city became to much, it was a but a short time before zoos were enveloped in more rapidly sprawling urban development.

For centuries zoos have provided unique opportunities for education, entertainment and research not found elsewhere in urban centers. Throughout time as knowledge of the natural kingdom changed and grew, zoos responded. Originally municipal institutions, zoo's initial responses to change were often conservative. Today, the majority of accredited zoos are operated by private and not for profit companies. As such, zoos now must compete for money and attention within urban and suburban settings. To woo visitors, zoos are changing in ways more radical than ever, creating and simulating entire environments in which the zoo visitor is immersed.

It has been over 40 years since the last major zoo reform, in a modern history that spans only 200 years. This analysis investigates the zoo in its urban context quantitatively and qualitatively, seeking to understand what the relationships are if there are any, between zoos and the cities that house them. Further, this analysis begins to investigate the fabric of zoos themselves.

- how regional, social, and cultural concepts of what is natural, wild, and exotic have influenced the construct of zoos, especially in their planar arrangement, animal exhibit space, and the type of interaction in which visitors can expect to participate.

- zoo exhibit typology, specifically in how they currently reinforce the human nature division, and how that division may be subverted.

From this information, I hope to gain an understanding that will lead to the design of a new zoo typology. The new zoo will reflect both its urban locale, as well as the broad scale changes in the natural environment worldwide.
